1.0 INTRODUCTION

1.1 OVERVIEW OF PROJECT

A Transit Project Assessment, based on the “Transit Projects and Greater Toronto Transportation Authority Undertakings, Ontario Regulation 231/08”, is being undertaken to study the implementation of a 23 kilometre bus rapid transit (BRT) system (the 407 Transitway) parallel to Highway 407 between Highway 400 and Kennedy Road in Vaughan, Richmond Hill and Markham, Ontario. The Transitway will be a grade-separated route consisting of a two lane roadway to be used solely by buses.

As part of the environmental assessment team, SENES Consultants Limited (SENES) was retained by the Ontario Ministry of Transportation (MTO) to complete a project-specific Noise and Vibration Impact Assessment (NVIA) to establish the noise and vibration impacts that may arise from the implementation of this undertaking. The preferred 407 Transitway alignment along the Highway 407 corridor from Highway 400 to Kennedy Road developed by Delcan Corporation was used for this Noise and Vibration Impact Assessment.

1.2 OVERVIEW OF NOISE AND VIBRATION IMPACT ASSESSMENT APPROACH

Noise from the 407 Transitway is assessed using protocols developed by the Ontario Ministry of Transportation (MTO). The general approach to the noise impact assessment is as follows:

- **Existing Conditions Scenario** – Predicting existing sound levels from road traffic;
- **Future No Build Scenario** – Predicting future sound levels at a 10 year horizon assuming that the 407 Transitway project does not proceed;
- **Future Build Scenario** – Predicting sound levels at a 10 year horizon assuming that the 407 Transitway project **does** proceed.

The difference in sound levels between the “future build” scenario and the “future no-build” scenario is an indicator of the noise impact of the project. The noise assessment protocol, described in Section 3.0, outlines criteria values and thresholds that define the degree of impact and the point at which mitigation must be considered.

The approach to the vibration impact assessment involved the review of vibration studies that SENES has completed for similar types of projects in the past, and assessing the likelihood for vibration impacts on sensitive land uses along the preferred route.

1.3 REPORT FORMAT

In addition to this introductory section, this noise and vibration impact assessment includes the following six (6) sections, as outlined in Table 1.1.

Table 1.1 Report Overview

Section	Description
1.0	STUDY AREA DESCRIPTION
3.0	REGULATORY REQUIREMENTS
4.0	ASSESSMENT METHODOLOGY
5.0	NOISE IMPACT ANALYSIS
6.0	VIBRATION IMPACT ANALYSIS
7.0	CONCLUSIONS

2.0 STUDY AREA DESCRIPTION

The preferred alignment for the 407 Transitway extends between Highway 400 and Kennedy Road. The majority of the alignment is parallel to the existing Highway 407; however, certain segments diverge and run parallel to Highway 7. A broad view of the entire preferred alignment is provided in Figure 2.1.

The 407 Transitway alignment is not contained entirely within a single municipality. The portion from the westerly limit to Yonge Street (approximately) is in the City of Vaughan; a small portion in the middle, approximately between Yonge Street and Bayview Avenue is in the Town of Richmond Hill; and the portion from Bayview Avenue to the easterly limit is in the Town of Markham. For the most part, the 407 Transitway study area consists of primarily 20th century urban development with commercial, industrial and residential areas, and linear transportation corridors such as roads and railway lines. The corridor primarily serves commuter traffic demands. Figures 2.2 and 2.3 show the existing land use designations within the west and east portions of the transitway. Since this assessment is based on preliminary design, land use designations were used as a guide to identify noise sensitive areas. During the Detailed Design phase of this project, detailed zoning information will be used if further noise assessment studies are required.

The boundary of the study area is defined as being approximately 500 m on either side of Highway 407 between Highway 400 and Kennedy Road. For the purposes of the noise and vibration assessment, only those receptors that are closest to the preferred 407 Transitway alignment were considered, as they represent the most impacted locations.

3.0 REGULATORY REQUIREMENTS

3.1 MTO ENVIRONMENTAL GUIDE FOR NOISE

In light of the potential for noise impacts from projects under jurisdiction of the MTO, a protocol has been prepared by the MTO to assist in the assessment of noise impacts for highway projects. This protocol applies to projects where the proposed route of a highway is near to NSAs. In order for a NSA to fall within the MTO definition, it must have an Outdoor Living Area (OLA). The MTO protocol defines OLAs and NSAs as follows:

Outdoor Living Area: An area at ground level, adjacent to an NSA and accommodating outdoor living activities. This area may be situated on any side of the NSA. The usual distance from the dwelling wall is 3 m. The vertical height is 1.2 m above the existing ground surface. Where unknown, the side closest to the highway should be assumed. Paved areas for multiple dwelling units may not be defined as an OLA.

Noise Sensitive Area:

- Private homes such as single family residences (owned or rental);
- Townhouses (owned or rental);
- Multiple unit buildings, such as apartments with OLAs for use by all occupants;
- Hospitals, nursing homes for the aged, where there are OLAs for all the patients;
- Educational facilities and day care centres, where there are OLAs for students;
- Campgrounds that provide overnight accommodation; and
- Hotels/motels where there are OLAs (i.e. swimming pool area, etc.) for visitors.

Land uses below, by themselves *do not* qualify as NSAs:

- Apartment balconies above ground floor;
- Churches;
- Cemeteries;
- Parks and picnic areas which are not part of an NSA;
- All commercial; and
- All industrial.

The MTO protocol requires that future sound levels with the proposed project be compared to the future sound levels without the project. If the result of this comparison is an increase in sound level above future ambient, then there may be a requirement to consider mitigation depending on the severity of the change. The future sound levels are to be predicted at a 10-year horizon beyond the full build-out year of the project being assessed. Table 3.1 summarizes the criteria for assessing whether mitigation is required.

Table 3.1 MTO Criteria for Noise Mitigation Assessment

Change in Noise Level Above Ambient / Projected Noise Level with Proposed Improvements	Mitigation Effort Required
< 5 dB change AND < 65 dBA	<ul style="list-style-type: none">• None
≥ 5 dB change OR ≥ 65 dBA	<ul style="list-style-type: none">• Investigate noise control measures on right-of-way;• Introduce noise control measures within right-of-way and mitigate to ambient if technically, economically and administratively feasible;• Noise control measures, where introduced, should achieve a minimum of 5 dB attenuation over first row receivers.

In short, if the increase above ambient due to the project is greater than 5 dB, or the resulting sound level at the NSA is greater than 65 dBA then mitigation must be considered. If the increase is less than 5 dB, then mitigation does not need to be considered provided that the sound level does not increase to greater than 65 dBA.

The MTO protocol requires that all sound levels used in the assessment be predicted using approved methodologies. The MTO currently accepts two methodologies. The Ontario Ministry of the Environment (MOE) Ontario Road Noise Analysis Method for Environment and Transportation (ORNAMENT) method is accepted for simple terrain, and where increases due to the proposed project are not expected to exceed 5 dB. The United States Federal Highway Administration (FHWA) STAMINA model may be used for more complex scenarios such as grade separations and sections of complex topography.

The MTO protocol includes several requirements for addressing noise from the construction of the undertaking. If there is potential for construction to impact any NSAs for reasons including (but not limited to) proximity and hours of operation, this must be identified along with potential mitigating measures. Mitigating measures may include (but not be limited to) timing constraints, minimum equipment setbacks, or quieter equipment. The MTO requires that the local by-laws be observed and exemptions sought, where possible, for any activities that may be restricted by the by-law. Where there is potential for noise impacts due to construction, the MTO protocol requires that a noise complaint process be implemented.

3.2 ONTARIO MINISTRY OF THE ENVIRONMENT NPC-115

Noise Pollution Control Publication 115 (MOE, 1978a) of the Ontario Model Municipal Noise Control By-Law stipulates specific sound emission standards for various pieces of construction equipment. This publication does not set receptor based sound level limits due to construction activities but rather sets limits for noise generated by each individual piece of equipment.

Table 3.2 lists Residential Area sound emission standards and Quiet Zone sound emission standards for specific items of new construction equipment based on their date of manufacture and power rating. Quiet zone and residential area sound emission standards for excavation equipment, dozers, loaders, backhoes or other related equipment are provided below:

Table 3.2 Sound Emission Standards Construction Equipment

Date of Manufacture	Power Rating Less than 75 kW (dBA)	Power Rating 75 kW and Larger (dBA)
January 1, 1979 to December 31, 1980	85	88
January 1, 1981 and after	83	85

3.3 ONTARIO MINISTRY OF THE ENVIRONMENT NPC-118

Noise Pollution Control Publication 118 (MOE, 1978b) of the Ontario Model Municipal Noise Control By-Law sets sound emission standards for motorized conveyances of various types. This publication does not set receptor based sound level limits due to heavy vehicle operation but sets limits for noise generated by each individual piece of equipment.

Table 3.3 lists for various years of manufacture, the sound emission standard for a heavy vehicle powered by a diesel engine. Heavy vehicle refers to a motorized conveyance having a registered gross weight of more than 4,500 kg.

Table 3.3 Sound Emission Standards for Heavy Vehicles

Date of Manufacture	Maximum Sound Level (dBA)
Prior to January 1, 1979	100
January 1, 1979 and after	95

¹ as measured in accordance with NPC - 103, Section 9

3.4 ONTARIO MINISTRY OF THE ENVIRONMENT NPC-205

Noise Pollution Control (NPC) Publication 205 (MOE, 1995) establishes sound level limits for stationary sources such as industrial and commercial establishments or ancillary transportation facilities, affecting points of reception in Class 1 and 2 Areas (Urban). NPC-205 states that the sound level limit must be established based on the principle of "predictable worst-case" noise impact. Generally, the limit is based on the background sound level at the receptors and must represent the minimum background sound level that occurs or is likely to occur during the operation of the stationary source under assessment.

Sound levels from steady stationary noise sources are quantified using the energy equivalent sound level, L_{eq} , in dBA. For urban areas, the daytime limit at a critical receptor for steady noise from a stationary source is the higher of either the one-hour L_{eq} resulting from existing volumes of road traffic and any industry that is not under investigation for noise excess, or 50 dBA. The night-time limit is the higher of either the ambient (road traffic plus industry) one-hour L_{eq} noise level, or 45 dBA. If the stationary source contains any noticeable features such as tonal components or buzzing, a 5 dB tonal penalty must be added to the noise level of the source as per NPC-104 (MOE, 1978c).

No restrictions apply to a stationary source resulting in a one hour L_{eq} lower than the minimum values for the time periods specified in Table 3.4.

Table 3.4 Minimum Values of One-Hour L_{eq} by Time of Day

Time of Day	One Hour L_{eq} (dBA)	
	Class 1 Area	Class 2 Area
07:00 - 19:00	50	50
19:00 - 23:00	47	45
23:00 - 07:00	45	45

3.5 CITY OF VAUGHAN – BY-LAW TO REGULATE NOISE (96-2006)

The City of Vaughan By-Law to Regulate Noise (City of Vaughan, 2006) applies to transportation projects mainly during the construction phase. The By-Law defines specific hours during which construction activities are allowed. The following excerpts from Section 10 of the By-Law describe the hours during which construction is prohibited:

- (1) *No person shall, between 1900 hours of one day and 0700 hours of the next day operate or cause to be operated, any construction vehicle or construction equipment in connection with the construction of any building or structure, highway, motor car, steam boiler or other engine or machine;*
- (2) *Despite subsection (1), no person shall operate or cause to be operated any construction vehicle or construction equipment before 0700 hours and no later than 1900 hours on any Saturday and not at all on Sunday or statutory holidays.*

If the construction is in a Quiet Zone (an area of 250 m radius around any hospital or seniors retirement facility), then the times quoted as 1900 hours in the above subsections change to 1700 hours.

Further to the above, the following general prohibition must be observed:

“The operation of any item of construction equipment shall not discharge into the open air, on any property other than a highway the exhaust except through a proper muffler or legal device, which effectively prevents loud or explosive noises.”

The By-Law does contain a provision to allow construction activities to be exempted from the requirements above. In order to qualify for an exemption, the construction equipment must comply with the sound level limits defined for construction equipment in the MOE publication NPC-115 (see section 3.2), and the activity for which exemption is sought must not exceed eleven (11) calendar days. Applications for exemption must be made sixty (60) days prior to the commencement of the construction activity.

3.6 TOWN OF RICHMOND HILL – NOISE BY-LAW (1055)

The Town of Richmond Hill By-Law 1055 (Town of Richmond Hill, 2008) includes requirements that apply to transportation projects during the construction phase. Construction activities are regulated by time and place restrictions, as well as a requirement for adequate muffling. The time and place restrictions are defined for Residential Areas and Quiet Zones. Quiet Zones are lands in which there are hospitals, nursing homes or senior citizen's housing. The times during which construction is prohibited in these two area types are identical, and are as follows:

- 7:00 p.m. one day to 7:00 a.m. next day; and
- All day Sundays and statutory holidays.

Further to this, section 1055.2.13 of the by-law prohibits “*the operation of any item of construction equipment in a quiet zone or residential area without effective muffling devices in good working order and in constant operation*”.

There is a provision in the by-law that allows for an application for exemption to be made for any restriction within the by-law. Exemptions, if granted, do not last longer than six (6) months unless a request for extension is granted.

3.7 TOWN OF MARKHAM – BY-LAW TO REGULATE NOISE (2003-137)

The Town of Markham Noise By-Law 2003-137 (Town of Markham, 2005) includes requirements that apply to transportation projects primarily during the construction phase. Section 3, subsections (1) and (2) of the By-Law identify general prohibitions and time restrictions that apply to construction projects. According to Section 3(1), the following is prohibited:

“the operation of construction equipment without effective muffling devices in good working order and constant operation.”

According to Section 3(2), the following time restrictions for construction activities must be observed in Quiet Zones and Residential Areas, which are areas defined in the Town of Markham Zoning By-Law:

- All day Sundays and Statutory Holidays; and
- 1900 one day to 0700 next day.

Further to the above, the Town of Markham requires the sound level limits in the applicable MOE NPC publications to be observed. The emission of sound resulting from the operation of construction equipment that is included in MOE publication 115 is prohibited within 600 m of a Residential Area, unless:

- a) the equipment was put into use prior to January 1, 1979; or
- b) the equipment bears a label affixed by the manufacturer or distributor, which states:
 - i. the year of manufacture; and
 - ii. that the equipment complies with the residential sound emission standards set out in Publication NPC-115, as applicable to that type of equipment and date of manufacture; or
- c) the owner, operator, manufacturer or distributor provides proof that the item of equipment complies with the residential sound emission standard set out in Publication NPC-115, as applicable to the type of equipment and date of manufacture.

Noise and Vibration Impact Assessment for the 407 Transitway (Highway 400 to Kennedy Road)

If the work area is located in a Quiet Zone, sound emission resulting from the operation of construction equipment that is included in MOE publication 115 is prohibited, unless:

- a) the equipment bears a label affixed by the manufacturer or distributor, which states:
 - i. the year of manufacture; and
 - ii. that the equipment complies with the residential sound emission standards set out in Publication NPC-115, as applicable to that type of equipment and date of manufacture.

The by-law also requires any motorized conveyance that is described in the MOE publication NPC-118 to comply with the sound level limits defined therein. This would apply to the operation of heavy vehicles (i.e., those greater than 4,500 kg), which would include buses.

There is a provision in the by-law that allows for an application for exemption to be made for any restriction within the by-law.

3.8 SUMMARY OF ASSESSMENT CRITERIA

Based on the information presented in the preceding Sections, the project noise assessment criteria are presented Table 3.5.

Table 3.5 Summary of Noise and Vibration Criteria

Component	Protocol	Criteria	Mitigation
Existing/ Future Noise	MTO	Future ambient noise levels without the influence of the proposed improvement	To be considered when criteria is exceeded by more than 5 dB, or when sound levels increase from <65 dBA to ≥65 dBA
	NPC-205	Stationary Sources; Day: 50 dBA Evening: 47 dBA Night: 45 dBA	To be implemented when criteria is exceeded
Construction Noise	NPC-115	See Table 3.2	Not addressed
	NPC-118	See Table 3.3	Not addressed
	City of Vaughan – Noise By-Law	Time and Place Restrictions; Requirement for Adequate Muffling	Not addressed
	Town of Richmond Hill – Noise By- Law	Time and Place Restrictions; Requirement for Adequate Muffling	Not addressed
	Town of Markham – Noise By-Law	Time and Place Restrictions; Requirement for Adequate Muffling; Compliance with NPC-115, NPC-118	Not addressed

4.0 ASSESSMENT METHODOLOGY

4.1 DOCUMENTATION REVIEW AND RECEPTOR SELECTION

The assessment began with a thorough review of the study area, including the proposed 407 Transitway alignment and the land uses along the corridor. Using aerial photography, NSAs were identified for inclusion in the assessment, based upon land use plans and proximity of sensitive land uses to the 407 Transitway route. The definition of an NSA provided in Section 3.1 was used to select receptor locations. In addition to existing NSAs, receptors were also included in the assessment where aerial photography indicated that an area was under development for residential use.

A total of eleven (11) receptors were selected for assessment, including nine (10) residential land uses and one (1) school (R1 – R10, and S1). The receptor locations are listed in Table 4.1. Aerial photographs illustrating the receptor locations are provided in Figure 2.1 and Appendix A. Two receptors, R7 and R9, were selected to represent future zoned noise sensitive land uses. The assessment of these receptors, as with all others, was based on the worst-case design with respect to outdoor environmental noise impact. It should be noted that the receptor located at the school does not meet the strict definition of an NSA according to the MTO definition, as there does not appear to be an OLA within 3 m of the building façade that faces the 407 Transitway. A receptor was considered here for informational purposes (i.e., as a worst-case scenario).

Table 4.1 Receptor Location Summary

Receptor ID	Receptor Type	Receptor Location	Approximate Distance to 407 Transitway (m)
R1	House	Hartley Court	102
R2	Townhouse	Yellowwood Circle	82
R3	House	Sassafras Circle	84
R4	House	Langstaff Road West	54
R5	House	Cedar Avenue	174
R6	Apartment	NE Corner of Bayview Ave and Hwy 7	121
R7	Future House	Future Development, South of South Park Rd	50
R8	House	Huntington Park Drive	267
R9	Future House	Future Development, NE Corner of Warden Ave and Highway 407	62
R10	House	Greenburg Gate	60
S1	School	St. Robert Catholic High School	31

4.2 TRAFFIC DATA AND ASSUMPTIONS

The existing 407 traffic volume data were provided by MTO. Annual growth rate used for future Highway 407 traffic projection was obtained from MTO's Greater Golden Horseshoe (GGH) Model. The assumption of truck percentage and split ratios on Highway 407 was approved by MTO before proceeding with the noise modelling. Projected bus volumes were also derived from the GGH Model. Using this information, IBI provided SENES with traffic data for future conditions (with and without the project) for Highway 407 and the 407 Transitway. Highway 407 was regarded as being the dominant source of background traffic noise in the area. Furthermore, the effect of Highway 7 was accounted for in the assessment at receptors R2, R3, R4, and R6 as these receptors are directly exposed to Highway 7. While receptors in the vicinity of R7 may also be exposed to noise from Highway 7, those with full exposure to the 407 Transitway will likely be shielded from Highway 7 by other homes in the development. The Highway 7 traffic data were provided by IBI as part of the previous environmental assessment for the York Region Rapid Transit Plan project.

The traffic volumes were provided as 24-hour totals for each segment of Highway 407 in the study area. The traffic data provided for Highway 407 were not categorized into the same vehicle classification descriptors as required by the MOE model used in the analysis (see Section 4.3); therefore, assumptions were made in order to reclassify the Highway 407 traffic data such that it could be used in the Ontario Road Noise Analysis Method for Environment and Transportation (ORNAMENT). The specific issue is that for Highway 407, traffic counts are provided for automobiles and two types of trucks, both of which are heavier than 4,500 kg but with no further description of how much heavier one type is versus the other. As will be discussed in Section 4.3, the MOE ORNAMENT method is very specific in how the two types of trucks are to be categorized with regard to gross weight. Therefore, an assumption was made to split the total trucks on Highway 407 into the classifications defined by ORNAMENT.

While the MTO provides typical percentages to apply in splitting a total truck volume between heavy and medium trucks where actual data is not available, these were not deemed appropriate for Highway 407 as it is a toll highway and has less truck traffic than a typical provincial freeway. For example, the MTO recommends that the total fleet volume on a freeway be assumed to be 20% trucks, and to split these at a ratio of 3:1 (heavy trucks to medium trucks). It was found that, on an average 24-hour basis over the study area, the total truck volume on the Highway 407 is approximately 7% of the total fleet. According to the MTO protocol, it would be expected that the ratio would lean less towards heavy trucks in instances where the total truck percentage decreases from 20% (i.e., for other types of highways, a 13% truck volume is to be assumed at a ratio of 3:2 for heavy trucks to medium trucks). Due to the uncertainty, it was conservatively assumed that there would be a slightly higher proportion of heavier trucks than

this 3:2 ratio predicts, and therefore a ratio of 2:1 (heavy trucks to medium trucks) was assumed. This assumption was approved by the MTO before proceeding with the modelling.

The existing traffic volumes (2008) as provided by IBI Group are provided in Appendix B, along with the annual growth percentages for each segment. Also provided in Appendix B are the projected traffic volumes to 2041 (10-year horizon beyond commencement of operation) and the re-classification of truck volumes as described above.

4.3 TRAFFIC NOISE MODELLING

4.3.1 STAMSON

The traffic sound levels were estimated using the STAMSON traffic noise model, which is based on the MOE ORNAMENT calculation method for traffic noise. Sound levels due to road noise include the contribution from three vehicle categories:

Automobiles

- All vehicles having two axles and four wheels designed primarily for the transportation of nine or fewer passengers or the transportation of cargo (e.g., vans and light trucks). Generally, the gross vehicle weight is less than 4,500 kg.

Medium Trucks

- All vehicles having two axles and six wheels designed for the transportation of cargo. Generally, the gross vehicle weight is greater than 4,500 but less than 12,000 kg. City buses are also included in this category.

Heavy Trucks

- All vehicles having three or more axles designed for the transportation of cargo. Generally, the gross vehicle weight is greater than 12,000 kg. Inter-city buses are included in this category.

Key parameters utilized by STAMSON in the calculation of road noise include vehicle speed, road surface, topography gradient, ground surface conditions (absorptive or reflective), angle of exposure, and the presence or absence of sound barriers. In order to predict sound levels for road traffic, the STAMSON model requires an hourly traffic flow of at least 40 vehicles/hour; travelling at least 40 km/h; and receptors must be located between 15 m and 500 m from the traffic source.

Due to the limitations of the STAMSON software, there was a need to make adjustments to a portion of the modelled results in order to arrive at representative sound levels for the future-build scenario under consideration. The limitation in STAMSON that resulted in further refinement of sound level predictions was:

- the restriction that the hourly traffic flow be greater than 40 vehicles per hour. During night-time hours, the total bus volume on the 407 Transitway is projected to 172 buses. Averaging this total over the 8-hour period results in 21.5 buses per hour.

Due to the above restriction, the 407 Transitway sound level impacts were modelled separately for each receptor point, and the night-time bus volumes were modelled at the minimum allowable by STAMSON – 320 buses over the 8-hour period. A further calculation was then performed on the night-time result to adjust the sound level downward to reflect the lower actual traffic volume. The expectation for a line source (i.e., a road) would be that if the traffic volume decreased by half, the calculated sound level at the receptor would reduce by 3 dB (with all other parameters such as vehicle speed, road surface type, etc. being equal). Since the traffic volume in this scenario is decreasing by slightly less than half, the reduction to the sound level would likewise be expected to decrease by slightly less than 3 dB. The following equation was used to calculate the actual reduction:

$$\text{Sound Level Reduction (dB)} = 10 \log \left[\frac{v_1}{v_2} \right]$$

where:

v_1 = actual traffic volume; and
 v_2 = modelled traffic volume.

Solving the above equation results in a reduction of 2.6 dB, which is the expected result.

It should be noted also that there are parking lots associated with several of the bus stations along the preferred route (described in Section 5.2). Many of these stations are not close to sensitive receptor locations; however there are two that are in close proximity to residences (GO Barrie Station and Leslie Station). While the MTO protocol does not include specific requirements with regard to assessment of parking lots, it was decided through discussion with MTO that the entrance/exit to these lots would be modelled and included in the future-build prediction for the nearest receptors. This modelling was completed in STAMSON. Due to the limitations of STAMSON, the vehicles were modelled as travelling at a speed of 40 km/hr (the minimum allowable input), which is likely to be an over-estimate resulting in conservatively high

predictions of noise impact. Traffic volume data for the parking lots were provided by IBI Group.

4.3.2 TNM

There was one instance in which the route of the 407 Transitway and surrounding terrain were too complex to model in STAMSON (receptor R4). For this reason, the FHWA Traffic Noise Model (TNM) was used. Specifically, the TNM algorithms that have been incorporated into a module for use within the Cadna-A sound propagation model by DataKustik were applied. The same vehicle classification categories as noted above for STAMSON apply to this model.

As with STAMSON, TNM utilizes information on the vehicle type, vehicle speed, and pavement type to predict receptor sound levels. The benefit of this software platform is that roads, receptors and barriers may be plotted in a graphical user interface in actual Universal Transverse Mercator (UTM) coordinates with the route plan and aerial photography as a base map underlay.

5.0 NOISE IMPACT ANALYSIS

The following section summarizes the results of the traffic noise modelling completed for the existing scenario, future no-build scenario and the future-build scenario. A summary of the analysis is provided along with an assessment of the need for mitigation. Also addressed in this section is the impact due to stationary sources (i.e., bus stations) and construction activities.

5.1 407 TRANSITWAY ASSESSMENT

As discussed in section 3.1, the predicted future sound levels resulting from the project are compared to the future ambient sound levels without the project. The MTO requires that future sound levels be predicted at 10 years beyond the full project build-out date which based on current information is predicted to be 2031. Therefore, all predictions of future sound levels are based on traffic projections for the year 2041. This includes traffic on Highway 407 as well as projected future bus volumes on the 407 Transitway.

Table 5.1 summarizes the predicted sound levels at each of the receptor locations for the various scenarios modelled, and provides an indication as to whether consideration to some form of mitigation is required according to the MTO protocol.

Table 5.1 Summary of Predicted Sound Levels

Receptor ID	Existing Conditions (dBA)	Future No-Build Ambient Sound Level (dBA)	Future-Build Sound Level (dBA)	Noise Impact due to Project (dB)	Increment Requiring Mitigation (dB)	Mitigation Consideration? (Yes/No)
R1	55.0	58.5	58.6	+0.1	5	No
R2	64.8	67.6	68.5	+0.9	5	Yes
R3	67.2	70.3	70.7	+0.4	5	Yes
R4 ¹	54.7	57.1	61.6	+4.5	5	No
R5	61.6	64.4	64.5	+0.1	5	No
R6	62.1	63.8	63.9	+0.1	5	No
R7	59.8	62.8	63.9	+1.1	5	No
R8	54.2	57.1	57.4	+0.3	5	No
R9	61.4	65.7	66.1	+0.4	5	Yes
R10	63.2	67.7	68.0	+0.3	5	Yes
S1	59.8	62.6	64.2	+1.6	5	No

1 – Modelled using the TNM module in Cadna-A due to complex grade separations, terrain and barrier locations

The results in Table 5.1 indicate that the sound level criteria are not exceeded by greater than 5 dB at any receptor point. Additionally, there are no instances in which future-build sound levels increase from <65 dBA to a value \geq 65 dBA. Any future-build sound levels that are shown to exceed 65 dBA also exceeded 65 dBA in the future no-build case as well. However, since the future no-build sound level at R2, R3, R9 and R10 are predicted to exceed 65 dBA, MTO will investigate the feasibility of installing noise mitigation at these receptors during the detailed design stage of the project.

The greatest impact is predicted to be at receptor R4, at which the predicted increase above the future no-build sound level is 4.5 dB. It should be noted that receptor R4 was not modelled in STAMSON due to the complexity of the study area at this location. The 407 Transitway separates from grade at this location, and turns north to pass over Highway 7 and Yonge Street before returning to grade. In this area Highway 7 is somewhat elevated on an earthen berm, which shields the residences represented by receptor R4 from Highway 407 to some extent. There is a barrier wall along the north side of Highway 7 that further shields the receptors from both Highway 7 traffic noise and Highway 407 traffic noise. Finally, the elevated sections of the 407 Transitway have a 1 m barrier wall on either side. Due to this complexity, the receptor sound levels were modelled using the FHWA TNM module in the Cadna-A software platform. In previous work completed for MTO (and reviewed by the MOE), SENES has used the more robust Cadna-A model for such situations in order to take these features into account.

Highway 7 and Yonge Street traffic data provided by IBI as part of the environmental assessment for the York Region Rapid Transit Plan project were utilized to provide a more complete picture of existing and future sound levels in this area (SENES, 2005a and 2005b). The traffic volumes were projected to the assessment years and modelled along with Highway 407 and the 407 Transitway. The projections were based on the annual growth rates from the previous project work for which this data were originally generated. The traffic volume and annual growth data are provided in Appendix B. Noise from Highway 7 was also accounted for at receptors R2, R3, and R6. While R7 (future development) is located near Highway 7, the effect of Highway 7 was not accounted for as the development is expected to shield those receptors closest to the 407 Transitway.

It was anticipated that receptor R4 would experience the greatest increase over future no-build sound levels, as the preferred routing for the 407 Transitway brings it approximately 50 m from the nearest residences. The proximity of the Transitway to the residences, combined with the elevated road segments in this area contribute to this increase. The 1 m barriers along the elevated sections of the 407 Transitway design help in reducing these impacts.

Other receptor locations are predicted to experience minimal increases in sound levels compared to the project future no-build levels. This is expected given the relatively low traffic volumes on the 407 Transitway, and the proximity of receptors to existing sources of traffic noise.

The predicted noise impact for receptor R1 includes the effect of the nearby parking lot for the GO Barrie bus station that is proposed for this area. As per guidance from MTO (verbal), the entrance/exit of the parking lot was modelled in STAMSON using traffic volumes provided by IBI. It was found that the impact due to the parking lot was minimal in comparison to background noise and noise from the 407 Transitway. The sound level due to the parking lot was predicted to be approximately 32 dBA on a 24-hr basis. As there are receptors in the area of the Leslie Station parking lot (albeit not as close as the GO Barrie (Concord) Station), a similar modelling study was completed in this area. This is included with the model outputs for R1 in Appendix D. As anticipated, the result was less than for the GO Barrie (Concord) Station and therefore the predicted impacts due to these lots are not considered to be significant.

Receptors R7 and R9 are each located in areas under development, and specific locations for modelling were selected based on where the maximum impact was likely to occur. Since the modelling was completed, a detailed layout of the development represented by R7 was made available which indicates that R7 is located much closer to the 407 Transitway than the actual location of the nearest sensitive buildings. Therefore, the predicted sound level impact at R7 is considered to be highly conservative for this area.

As was noted above, the future noise level at R9 is expected to exceed 65 dBA; therefore, the MTO will investigate the feasibility of installing noise mitigation at this receptor during the detailed design stage of the project. While the future noise level at R9 is predicted to be less than 65 dBA, it exceeds 55 dBA. Since R7 is a potential location for future noise sensitive development, MOE noise guidelines require that a sound barrier should be investigated at this location. As the actual construction date of the project is likely to be in the distant future, the MTO will revisit the noise predictions at a point closer to the actual project construction. The MTO will ensure that the project complies with the appropriate noise policy of the day and will re-investigate and provide noise mitigation if it is required in the future.

A summary of traffic data, calculations and results for each receptor are provided in Appendix C. The STAMSON model output files are provided in Appendix D. Please note that the sound levels shown in Table 5.1 above are 24-hour L_{eq} sound levels as required by the MTO guide. The STAMSON outputs, as shown in Appendix D, are presented as 16-hr and 8-hr L_{eq} sound levels in case further details are sought on day/night levels. The 16-hr and 8-hr L_{eq} sound levels from the STAMON outputs were combined to provide the 24-hr L_{eq} sound levels shown in the table. Furthermore, as was noted earlier, the night-time bus volume on the 407 Transitway was too low to be modelled in STAMSON therefore a correction for the 407 Transitway sound levels

had to be accounted for outside of the STAMSON model. Calculation details are provided in Appendix C.

Due to curvature on sections of Highway 407 and the proposed 407 Transitway, it was not possible to model all sections of these roadways as being straight and flat with full exposure to all receptors. Angles of exposure were utilized as necessary to account for the curved sections of Highway 407 and the proposed 407 Transitway (i.e., the roads were split into smaller segments to account for the curve, limited by the associated angle of exposure for each segment). Angles of exposure were also used where there was a change in traffic volumes on the road being modelled, or where the grade changed on the road being modelled.

5.2 STATIONARY SOURCE NOISE IMPACT

The MTO protocol requires that any stationary sources that are considered part of the project be included in the analysis. The assessment of these stationary sources is to be in accordance with the MOE guidance provided in their publication NPC-205.

The 407 Transitway includes seven (7) bus stations where buses will temporarily idle to allow passengers to board/alight the buses. Three (3) of the bus stations are considered main intermodal stations (Spadina subway/Jane, Yonge/Richmond Hill Centre and Kennedy stations) which will connect with larger transportation systems such as proposed subway line extensions. It is important to note that these intermodal bus facilities are not being proposed as part of the current undertaking; they are being proposed by the TTC in the case of Jane and Yonge Stations, and York Region's Viva Program in the case of Kennedy Station. The remaining four (4) stations will be smaller stations where buses will stop for very short periods to allow passengers to get on and off. All bus stations will include added parking lots and some will have passenger pick-up and drop-off (PPUDO) areas. These stations will not have any significant stationary noise sources associated with them (i.e., ventilation exhaust fans), as they are generally small enclosures with staircases and/or other means of allowing passengers to access the bus platforms from street level and vice versa. Refer to Appendix F for the 60% preliminary design bus station plans from Delcan.

It should be noted that the impact of Yonge/Richmond Hill Centre Station, which is an intermodal station connecting to the Yonge subway line extension, has already been assessed as part of a previous Environmental Assessment (SSWA, 2009). That assessment predicted no noise impacts from this station. Additionally, a station in close vicinity to the proposed location of Spadina subway/Jane Station (another intermodal station, connecting to the Spadina subway extension) was assessed previously (SSWA, 2006) and no noise impacts were predicted. The reasons cited in both assessment reports for there being no predicted noise impacts from these

stations were a combination of setback distance from sensitive land uses and high ambient sound levels due to existing traffic.

At the Spadina subway/Jane Station site, an Operations and Maintenance (O&M) Facility is proposed. The proposed location for Spadina subway/Jane Station is approximately 700 m from the nearest sensitive land use, being a hotel on the opposite (north) side of Highway 407. According to Delcan, there will be minimal ventilation fans associated with the O&M facility. As the assessment of stationary sources is to be in accordance with MOE requirements, the MOE Primary Noise Screening Form was completed for this facility, resulting in a minimum required separation distance of 400 m. Given the actual 700 m setback distance, the O&M facility is anticipated to have no significant noise impact on the nearest sensitive receptor. A Certificate of Approval will be sought for this facility during the permitting process.

5.3 CONSTRUCTION NOISE IMPACT

It is likely the construction of the 407 Transitway will cause nearby receptor sound levels to increase above ambient conditions, due to proximity. Construction activities are temporary in nature, but would be considered a source of annoyance if construction occurs outside of normal weekday construction periods when ambient sound levels are the lowest.

Time and place restrictions as described in the various noise by-laws for the municipalities through which the 407 Transitway will pass have been outlined in Section 3.0. Construction must either occur within these limitations, or exemptions must be sought prior to commencement of construction. Furthermore, all construction equipment is required to be properly maintained to limit noise emissions. The noise limits for construction equipment are stipulated in the MOE NPC-115 and NPC-118 guidelines, as described in Section 3.0. As there is potential for noise impacts from construction, the MTO requires that a protocol be implemented to respond to noise complaints during the construction phase.

6.0 VIBRATION IMPACT ANALYSIS

SENES has completed vibration impact assessments for similar project types (bus transit) in urban settings. In particular, SENES completed a vibration assessment along the Highway 7 corridor in 2005 as part of the York Rapid Transit Plan (YRTP) (SENES, 2005b). The results of the assessment demonstrated that vibration levels from existing traffic were not perceptible at the closest sensitive receptors (generally well below 0.1 mm/s). Based on SENES' experience, this is the expected result as the traffic volume generally consists of rubberized-tire vehicles. The vibration levels from such traffic are typically negligible, with the exception of instances in which there is an expansion joint in the roadbed.

As the buses operating on the 407 Transitway will also be rubberized-tire vehicles travelling on a smooth surface, it is not anticipated that their operation will contribute significantly to existing vibration levels in the study area.

7.0 CONCLUSIONS

The following key conclusions are drawn from the preceding information:

- Highway 407 and Highway 7 are the existing dominant noise sources at receptor locations along the proposed 407 Transitway.
- The 407 Transitway is predicted to cause minimal increases above future no-build sound levels (< 5 dB increase) at all receptor locations. Highway 407 and Highway 7 are predicted to continue to dominate the future sound environment at these receptors.
- There are four receptors, namely R2, R3, R9 and R10, where the future no-build sound levels are predicted to exceed 65 dBA. While the predicted incremental noise from the proposed 407 Transitway at each of these receptors is less than 1 dB, that is, well below the 5 dB increase permitted by the MTO Guide, the MTO will investigate the feasibility of installing noise mitigation at these receptors during the detailed design stage of the project.
- As the actual construction date of the project is likely to be in the distant future, the MTO will revisit the noise predictions at certain receptors closer to the time of construction and provide noise mitigation if it is required in the future. The MTO will ensure that the project complies with the appropriate noise policy of the day.
- There are three intermodal bus facilities within the 407 Transitway corridor at Jane Street, Yonge Street and Kennedy Road that are potential sources of stationary noise. It is important to note, however, that these intermodal bus facilities are not being proposed as part of the current undertaking; they are being proposed by the TTC in the case of Jane and Yonge Stations, and York Region's Viva Program in the case of Kennedy Station. In any case, previous noise studies completed for these bus facilities indicate that they are unlikely to cause a noise impact at any of the receptor locations.
- Construction should be limited to the time and place restrictions outlined in the various applicable municipal noise by-laws, or an exemption must be sought prior to commencement of construction. Furthermore, all construction equipment should be properly maintained to limit noise emissions and comply with the noise limits outlined in NPC-115 and NPC-118 guidelines.
- As construction has potential to impact receptors due to proximity, the MTO requires that a protocol be implemented to respond to complaints.
- Based on previous project experience with respect to bus transit in the Highway 7 corridor, there are no expected vibration impacts resulting from the operation of the 407 Transitway. Generally, vehicles with rubber tires operating on smooth paved surfaces do not contribute significantly to ground-borne vibration levels.

Yonge Street Traffic Volume Estimation (for R4 Modelling)

Data based on 33434 - York Rapid Transit - Yonge St Noise Study (June 2005 Report)

2001 AADT for Yonge St (between 407EB Off-Ramp and Garden Ave): 31,980
2003 AADT for Yonge St (between 407EB Off-Ramp and Garden Ave): 32,490

Annual Growth Rate: 0.79%

2041 AADT for Yonge St (between 407EB Off-Ramp and Garden Ave): 43,884

Percent Automobiles: 96%
Percent Medium Trucks: 4%
Percent Heavy Trucks: 0%

Day/Night Split: 60/40

Daytime Hourly Traffic Volume (one direction): 823
Night-time Hourly Traffic Volume (one direction): 1097

2008 AADT for Yonge St (between 407EB Off-Ramp and Garden Ave): 33,801

Daytime Hourly Traffic Volume (one direction): 634
Night-time Hourly Traffic Volume (one direction): 845

Highway 7 Traffic Volume Estimation (for R4 Modelling)

Data based on 33434 - Highway 7 Corridor and Vaughan N-S Link Noise Study (August 2005 Report)

2021 AADT for Highway 7 (between Bathurst St and Yonge St): 49,536

20-Year Growth
Rate: 16.5%

2041 AADT for Highway 7 (between Bathurst St and Yonge St): 57,709

Percent
Automobiles: 94.5%
Percent Medium
Trucks: 2.3%
Percent Heavy
Trucks: 3.3%

Day/Night
Split: 90/10

Daytime Hourly Traffic Volume (both directions): 3246
Night-time Hourly Traffic Volume (both directions): 721

2001 AADT for Highway 7 (between Bathurst St and Yonge St): 42,520

Annual Growth Rate: 0.77%

2008 AADT for Highway 7 (between Bathurst St and Yonge St): 44,855

Daytime Hourly Traffic Volume (both directions): 2,523
Night-time Hourly Traffic Volume (both directions): 561

Highway 7 Traffic Volume Estimation (Receptors R2, R3)

Data based on 33434 - Highway 7 Corridor and Vaughan N-S Link Noise Study (August 2005 Report)

2001 AADT for Highway 7 (between Bathurst St and Dufferin St): 35,115

2021 AADT for Highway 7 (between Bathurst St and Dufferin St): 50,390

20-Year Growth Rate: 43.5%

Annual Growth Rate: 1.82%

2041 AADT for Highway 7 (between Bathurst St and Dufferin St): 72,310

¹ - STAMSON cannot model a traffic volume that is less than 40 vehicles per hour. The night (8-hour) bus volume of 174 is less than 40 vph, therefore it was modelled at the minimum of 320 vehicles in an 8-hour period and adjusted.

TW7	-82 to -58	100	48	48	1.2	1.2	1,189	-	1,189	-	174	-	174	-

1 - STAMSON cannot model a traffic volume that is less than 40 vehicles per hour. The night (8-hour) bus volume of 174 is less than 40 vph, therefore it was modelled at the minimum of 320 vehicles in an 8-hour period and adjusted

Description: Receptor R3 - Highway 407

Road data, segment # 1: 407EB1 (day/night)

Car traffic volume : 104297/6050 veh/TimePeriod
Medium truck volume : 2657/359 veh/TimePeriod
Heavy truck volume : 5314/719 veh/TimePeriod
Posted speed limit : 100 km/h
Road gradient : 0 %
Road pavement : 1 (Typical asphalt or concrete)

Data for Segment # 1: 407EB1 (day/night)

Angle1 Angle2 : 50.00 deg 90.00 deg
Wood depth : 0 (No woods.)
No of house rows : 0 / 0
Surface : 2 (Reflective ground surface)
Receiver source distance : 173.00 / 173.00 m
Receiver height : 1.20 / 1.20 m
Topography : 4 (Elevated; with barrier)
Barrier angle1 : 50.00 deg Angle2 : 90.00 deg
Barrier height : 3.00 m
Elevation : 3.00 m
Barrier receiver distance : 113.00 / 113.00 m
Source elevation : 0.00 m
Receiver elevation : 3.00 m
Barrier elevation : 0.00 m
Reference angle : 0.00

Noise and Vibration Impact Assessment for the 407 Transitway (Highway 400 to Kennedy Road)

Page 2

Road data, segment # 2: 407EB2 (day/night)

Car traffic volume : 104297/6050 veh/TimePeriod
Medium truck volume : 2657/359 veh/TimePeriod
Heavy truck volume : 5314/719 veh/TimePeriod
Posted speed limit : 100 km/h
Road gradient : 0 %
Road pavement : 1 (Typical asphalt or concrete)

Data for Segment # 2: 407EB2 (day/night)

Angle1 Angle2 : -80.00 deg 43.00 deg
Wood depth : 0 (No woods.)
No of house rows : 0 / 0
Surface : 2 (Reflective ground surface)
Receiver source distance : 172.00 / 172.00 m
Receiver height : 1.20 / 1.20 m
Topography : 4 (Elevated; with barrier)
Barrier angle1 : -80.00 deg Angle2 : 43.00 deg
Barrier height : 3.00 m
Elevation : 3.00 m
Barrier receiver distance : 113.00 / 113.00 m
Source elevation : 0.00 m
Receiver elevation : 3.00 m
Barrier elevation : 0.00 m
Reference angle : 0.00

Road data, segment # 3: 407WB1 (day/night)

Car traffic volume : 96485/6849 veh/TimePeriod
Medium truck volume : 2671/214 veh/TimePeriod
Heavy truck volume : 5341/429 veh/TimePeriod
Posted speed limit : 100 km/h
Road gradient : 0 %
Road pavement : 1 (Typical asphalt or concrete)

Data for Segment # 3: 407WB1 (day/night)

Angle1 Angle2 : 50.00 deg 90.00 deg
Wood depth : 0 (No woods.)
No of house rows : 0 / 0
Surface : 2 (Reflective ground surface)
Receiver source distance : 129.00 / 129.00 m
Receiver height : 1.20 / 1.20 m
Topography : 4 (Elevated; with barrier)
Barrier angle1 : 50.00 deg Angle2 : 90.00 deg
Barrier height : 3.00 m
Elevation : 3.00 m
Barrier receiver distance : 113.00 / 113.00 m
Source elevation : 0.00 m
Receiver elevation : 3.00 m
Barrier elevation : 0.00 m
Reference angle : 0.00

Noise and Vibration Impact Assessment for the 407 Transitway (Highway 400 to Kennedy Road)

Page 3

Road data, segment # 4: 407WB2 (day/night)

Car traffic volume : 96485/6849 veh/TimePeriod

Noise and Vibration Impact Assessment for the 407 Transitway (Highway 400 to Kennedy Road)

STAMSON 5.0 NORMAL REPORT Date: 13-05-2010 13:04:36
MINISTRY OF ENVIRONMENT AND ENERGY / NOISE ASSESSMENT

Filename: r5olatw.te Time Period: Day/Night 16/8 hours
Description:

Road data, segment # 1: TW1 (day/night)

Car traffic volume : 0/0 veh/TimePeriod
Medium truck volume : 1189/320 veh/TimePeriod
Heavy truck volume : 0/0 veh/TimePeriod
Posted speed limit : 100 km/h
Road gradient : 5 %
Road pavement : 1 (Typical asphalt or concrete)

Data for Segment # 1: TW1 (day/night)

Angle1 Angle2 : -66.00 deg -58.00 deg
Wood depth : 0 (No woods.)
No of house rows : 0 / 0
Surface : 1 (Absorptive ground surface)
Receiver source distance : 126.00 / 126.00 m
Receiver height : 1.20 / 1.20 m
Topography : 4 (Elevated; with barrier)
Barrier angle1 : -66.00 deg Angle2 : -58.00 deg
Barrier height : 2.00 m
Elevation : 2.00 m
Barrier receiver distance : 118.00 / 118.00 m
Source elevation : 0.00 m
Receiver elevation : 2.00 m
Barrier elevation : 0.00 m
Reference angle : 0.00

Noise and Vibration Impact Assessment for the 407 Transitway (Highway 400 to Kennedy Road)

Road data, segment # 4: TW4 (day/night)

Car traffic volume : 0/0 veh/TimePeriod
Medium truck volume : 1189/320 veh/TimePeriod
Heavy truck volume : 0/0 veh/TimePeriod
Posted speed limit : 100 km/h
Road gradient : 0 %
Road pavement : 1 (Typical asphalt or concrete)

Data for Segment # 4: TW4 (day/night)

Angle1 Angle2 : 8.00 deg 48.00 deg
Wood depth : 0 (No woods.)
No of house rows : 0 / 0
Surface : 1 (Absorptive ground surface)
Receiver source distance : 180.00 / 180.00 m
Receiver height : 1.20 / 1.20 m
Topography : 1 (Flat/gentle slope; no barrier)
Reference angle : 0.00

Road data, segment # 5: TW5 (day/night)

Car traffic volume : 0/0 veh/TimePeriod
Medium truck volume : 1189/320 veh/TimePeriod
Heavy truck volume : 0/0 veh/TimePeriod
Posted speed limit : 100 km/h
Road gradient : 1 %
Road pavement : 1 (Typical asphalt or concrete)

Data for Segment # 5: TW5 (day/night)

Angle1 Angle2 : 44.00 deg 90.00 deg
Wood depth : 0 (No woods.)
No of house rows : 0 / 0
Surface : 1 (Absorptive ground surface)
Receiver source distance : 195.00 / 195.00 m
Receiver height : 1.20 / 1.20 m
Topography : 1 (Flat/gentle slope; no barrier)
Reference angle : 0.00

Noise and Vibration Impact Assessment for the 407 Transitway (Highway 400 to Kennedy Road)

USING PROPOSED FUTURE ROAD

LEGEND

- 

A legend on the left side of the map, listing eight categories with corresponding symbols:

 - SITE BOUNDARY: A red dashed line.
 - STREETS / HIGHWAYS: Two parallel yellow lines.
 - CREEK / WATER BODY: A blue line.
 - WOODLOT: A green area filled with black dots.
 - 407 BRT ROUTE: A thick blue line.
 - HYRDO TOWER / HYDRO POL: A symbol consisting of a square with a circle inside, connected by a line to a small circle.
 - POTENTIAL T.O.D.: A series of five pink rectangles of increasing height.
